---

# About me

## Lev Epshtein

Technology enthusiast with 15 years of industry experience in DevOps and IT. Industry experience with back-end architecture.

Solutions architect with experience in big scale systems hosted on AWS/GCP, end-to-end DevOps automation process.

Cloud DevOps, and Big Data instructor at NAYA and JB.

Certified GCP trainer,

Partner & Solution Architect Consultant at Opsguru.

**lev@opsguru.io**

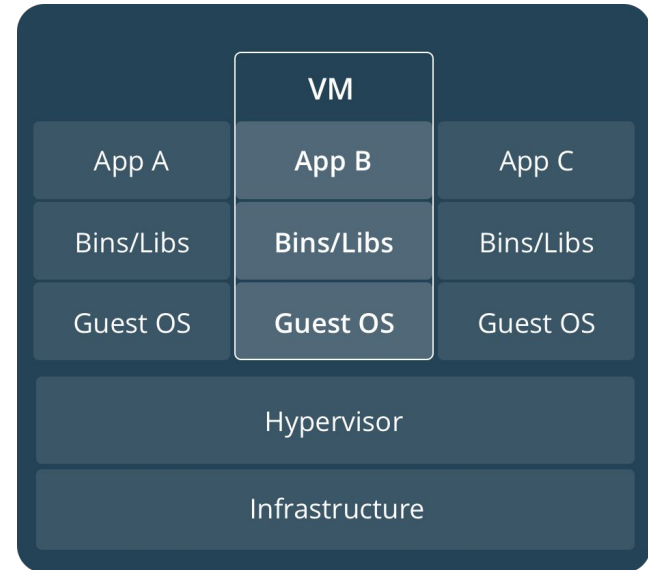

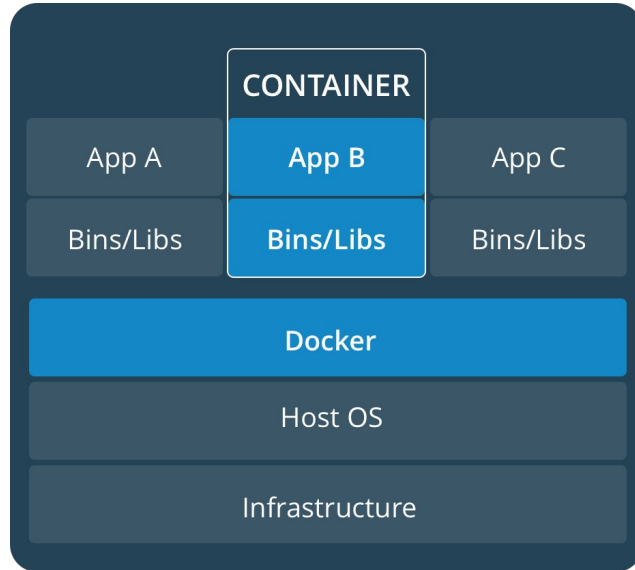

---

# Docker

# What is Docker?

- Docker is an open platform for developing, shipping, and running applications.
- Docker allows you to package an application with all of its dependencies into a standardized unit for software development.
- The use of containers to deploy applications is called ***containerization***.

# Containers and Virtual machines

---

# Docker Benefits Upon VMs

- **Small to tiny images** - Few hundred MB's for OS + Application (5MB for full OS - Alpine) VS. Gigabytes in VM's
- **Very small footprint on the host machine** (CPU, RAM Impact) as Docker only use what it required instead of building a complete Operating system per VM.
- **Containers use up only as many system resources as they need at a given time.** VMs usually require some resources to be permanently allocated before the virtual machine starts.
- **Direct hardware access.** Applications running inside virtual machines generally cannot access hardware like graphics cards on the host in order to speed processing. Containers Can (ex. Nvidia )
- **Microservice in nature and integrations** (API's) for whatever task required.
- **Portable, Fast** (Deployments , Migration , Restarts and Rollbacks) and **Secure**
- **Can run anywhere and everywhere**
- **Simplify DevOps**
- **Version controlled**
- **Open Source**

---

# Common Use Case for Docker

- CI / CD
- Fast Scaling application layers for overcoming application performance limitations.
- For Sandboxed environments (Development, Testing , Debugging)
- Local development environment ( no more “ It ran on my laptop...” )
- Infrastructure as a CODE made easy with docker
- Multi-Tier applications (Front End , Mid Tier (Biz Logic) , Data Tier) / Microservices
- Building PaaS , SaaS

---

# Docker Architecture

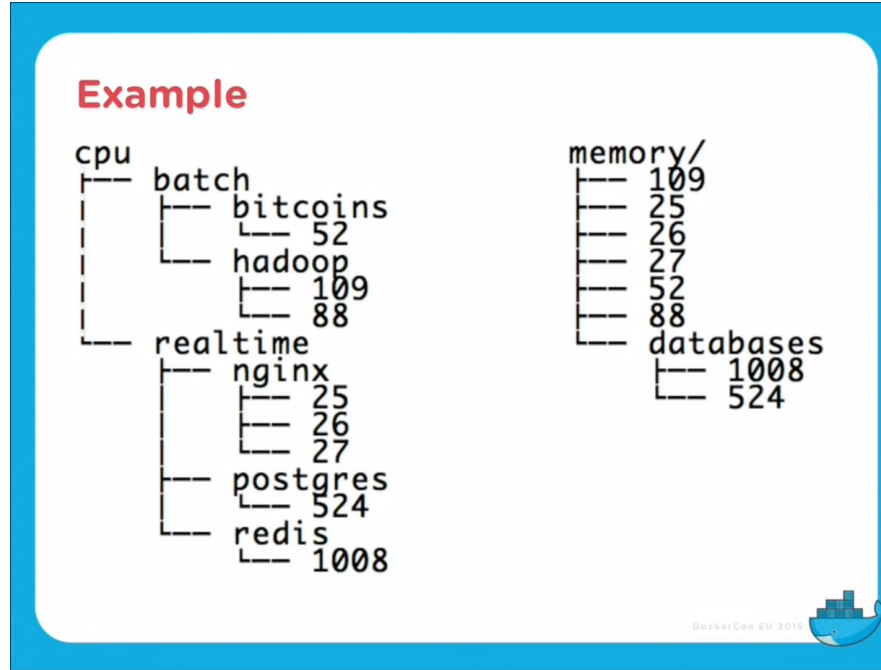

# Under The Hood

- Architecture: Linux X86-64
- Written in: GoLang ( On March 13, 2014, with the release of version 0.9, Docker dropped LXC as the default execution environment which is an operating system level virtualization and replaced it with its own libcontainer library written in the Go programming language )
- Engine: Client - Server (Daemon) Architecture
- Namespace: Isolation of process in linux where one process cant “See” the other process
- Control Groups: Linux Kernel capability to limit and isolate the resource usage (CPU, RAM, disk I/O, network etc..) of a collection of process
- Container format: libcontainer - Go implementation for creating containers with namespaces, control groups and File system capabilities access control

# Containers Cgroups

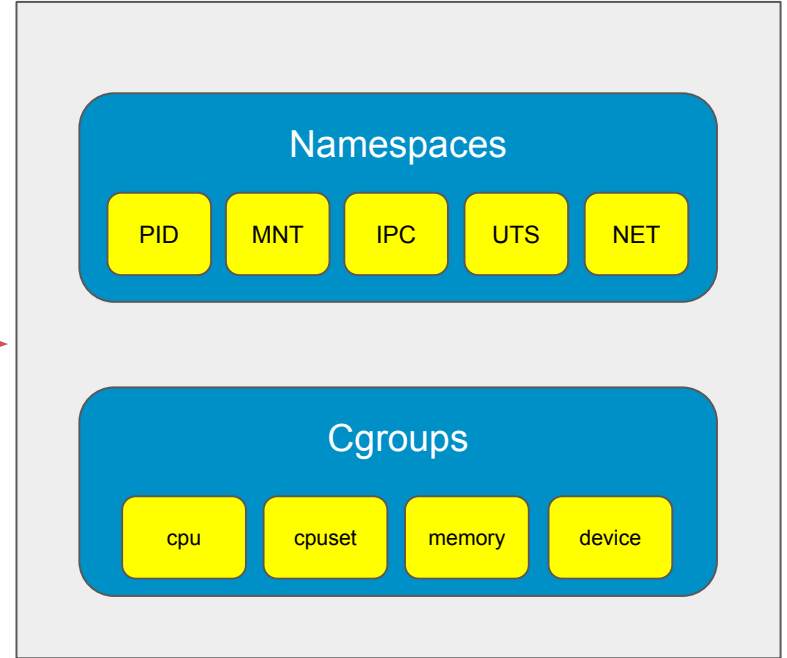

Cgroup

Container

# Docker Architecture

## Overview

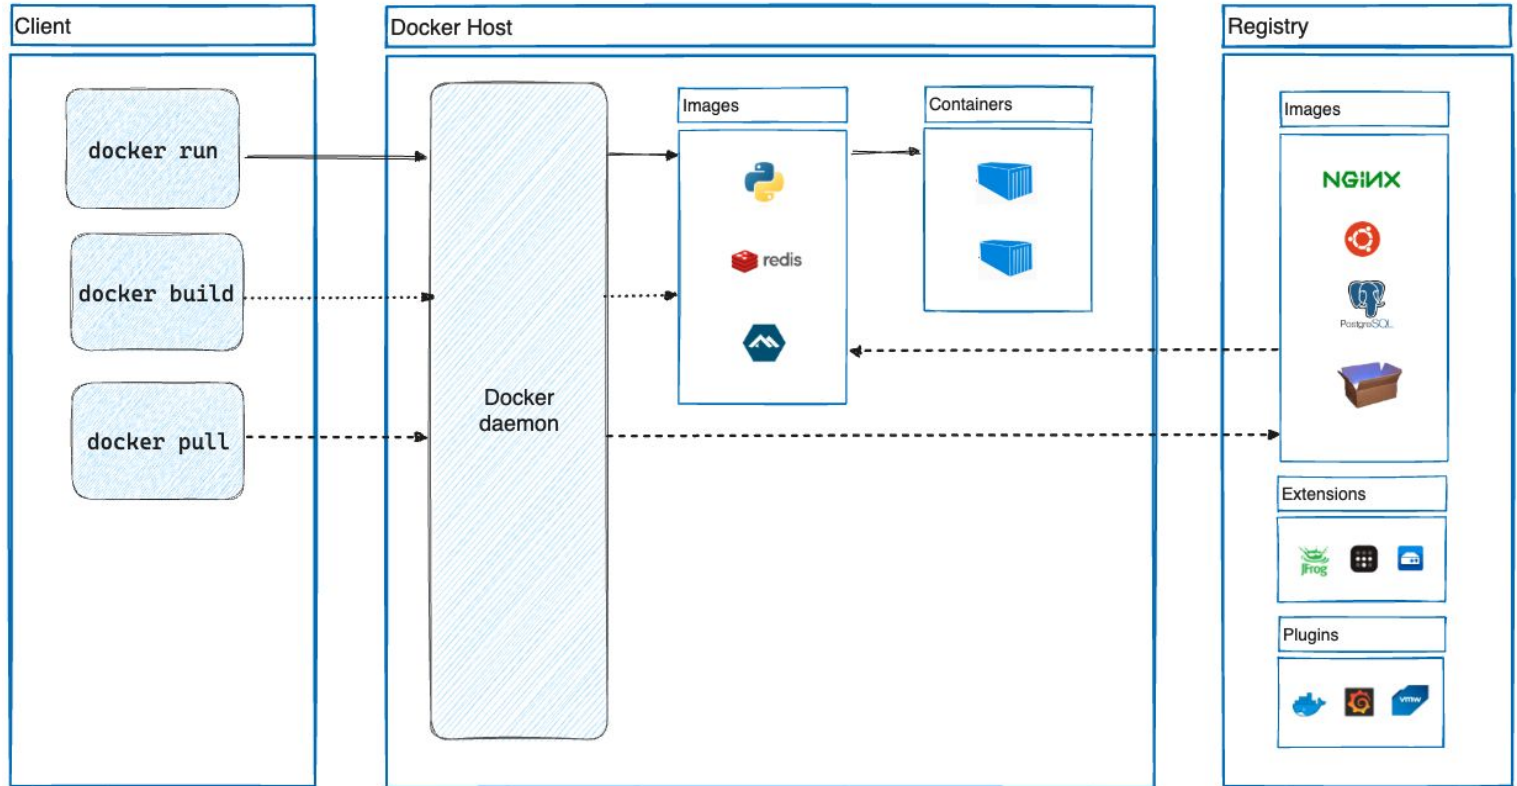

---

# What is docker - Technical Aspect

## Docker Architecture

Docker uses a client-server architecture. The Docker *client* talks to the Docker *daemon*, which does the heavy lifting of building, running, and distributing your Docker containers. The Docker client and daemon *can* run on the same system, or you can connect a Docker client to a remote Docker daemon. The Docker client and daemon communicate using a REST API, over UNIX sockets or a network interface.

# The Docker Architecture

---

# Docker Components

- Engine
- Daemon
- (Docker) Client
- Docker Registries
- Docker Objects
- Machine
- Compose

# Docker Components

## Engine

- A server which is a type of long-running program called a daemon process (the dockerd command).
- A REST API which specifies interfaces that programs can use to talk to the daemon and instruct it what to do.
- A command line interface (CLI) client (the docker command).

# Docker Components

## Daemon

- The Docker daemon (dockerd) listens for Docker API requests and manages Docker objects such as images, containers, networks, and volumes. A daemon can also communicate with other daemons to manage Docker services.

# Docker Components

## Docker Client

- The Docker client (docker) is the primary way that many Docker users interact with Docker. When you use commands such as docker run, the client sends these commands to dockerd, which carries them out. The docker command uses the Docker API. The **Docker client can communicate with more than one daemon.**

# Docker Components

## Docker Registries

- A Docker registry stores Docker images. Docker Hub and Docker Cloud are public registries that anyone can use, and Docker is configured to look for images on Docker Hub by default. You can even run your own private registry.
- When one use “docker pull / push / run” commands, the required images are pulled from the configured registry.

# Docker Components

## Docker Objects

### 1. Images

- a. Read Only template with instruction for creating a Docker Container. Often, an Image is based on another image with some additional customization.
- b. Self own images that are fully created by you using DockerFile with a simple syntax where every instruction control a different Layer in the image. Once a change is made to a specific layer, a rebuild of the image will change only the updated layers. This what makes images small, fast and lightweight in compared to other virtualization solutions

# Docker Components

## Docker Objects

### 1. Containers

- a. A container is a runnable instance of an image. You can create, start, stop, move, or delete a container using the Docker API or CLI. You can connect a container to one or more networks, attach storage to it, or even create a new image based on its current state.
- b. Container is defined by its image as well as any configuration options we provide to it when created or when we start it

# Docker Components

## Docker Objects

### 1. **Services**

- a. Allow you to scale containers across multiple Docker daemons, which all work together as a swarm with multiple managers and workers. Each member of a swarm is a Docker daemon, and the daemons all communicate using the Docker API. A service allows you to define the desired state, such as the number of replicas of the service that must be available at any given time. By default, the service is load-balanced across all worker nodes. To the consumer, the Docker service appears to be a single application. Docker Engine supports swarm mode in Docker 1.12 and higher.

---

# Docker Components

## Docker Compose

A tool for defining and running complex applications with Docker (eg multi-container application ex. LAMP)  
With a single file.

# The underlying technology

Written in Go and takes advantage of several of the Linux kernel features:

- **Namespaces**
  - Provide the isolated workspace called the container. When you run a container, Docker creates a set of namespaces for that container.
- **Control groups (cgroups)**
  - Allow you to limit the access processes and containers have to system resources such as CPU, RAM, IOPS and network.

---

# Let's Start

git clone <https://github.com/lelep/solaredge-k8s-course.git>

---

# Docker Flow

```
> docker run -i -t -d --name dockerlearning -p 8080:80 alpine:latest sh
```

‘**docker run**’ will run the container

This will not restart an already running container, just create a new one

**docker run** [options] **IMAGE** [command] [arguments]

[options] modify the docker process for this container

IMAGE is the image to use

[command] is the command to run inside the container (entry point to hold the container running)

[arguments] are arguments for the command

# Docker Flow

```
> docker run -i -t -d --name dockerlearning -p 8080:80 alpine:latest sh
```

‘docker run’ will run the container:

-i - Interactive mode

-t - Allocate pseudo TTY - or not Terminal will be available

-d - Run in the background (Daemon style)

--name - Give the container a name or let Docker to name it

-p [local port] : [container port] - Forward local port to the container port

| CONTAINER ID | IMAGE         | COMMAND | CREATED                | STATUS      | PORTS                | NAMES          |
|--------------|---------------|---------|------------------------|-------------|----------------------|----------------|
| 98debfed4458 | alpine:latest | "sh"    | Less than a second ago | Up 1 second | 0.0.0.0:8080->80/tcp | dockerlearning |

# Docker Flow

```
> docker run -i -t -d --name dockerlearning -p 8080:80 alpine:latest sh
```

- Pulls the alpine:latest image from the registry (if not existed on our station)
  - Run “docker images” to see what images already downloaded / in use locally
- Creates new container
- Allocate FS and Mounts a read-write Layer
- Allocates network/bridge interface
- Set up an IP Address
- Executes a process that we specify (in this scenario - “sh” as alpine release doesn't have bash)
- Captures and provides application outputs

# Common Docker Commands

```
> docker run -h MyDocker -i -t --rm debian /bin/bash
```

- docker run will run the container
  - -h - Container host name
  - --rm - Automatically remove the container when it exits
- docker exec/atatch

```
> docker exec -it <CONTAINER> ash
```

```
> docker attach <CONTAINER> ,.. (Ctrl P + Ctr Q to quit)
```

# Common Docker commands

## // General info

man docker // man docker-run  
docker help // docker help run  
docker info  
docker version  
docker network ls  
docker volumes ls

## // Images

docker images // docker [IMAGE\_NAME]  
docker pull [IMAGE] // docker push [IMAGE]

## // Containers

docker run  
docker ps // docker ps -a, docker ps -l  
docker stop/start/restart [CONTAINER]  
docker stats [CONTAINER]  
docker top [CONTAINER]  
docker port [CONTAINER]  
docker inspect [CONTAINER]  
docker inspect -f "{{ .State.StartedAt }}"  
[CONTAINER]  
docker rm [CONTAINER]

# Running Mysql On docker

1. Execute:

```
docker run -p 13306:3306 --name mysql-docker-local -eMYSQL_ROOT_PASSWORD=Password -d mysql:latest
```

2. ssh to running container and check mysql is running.

**STOP AND REMOVE**  
CLEAN UP

---

# Docker Volumes

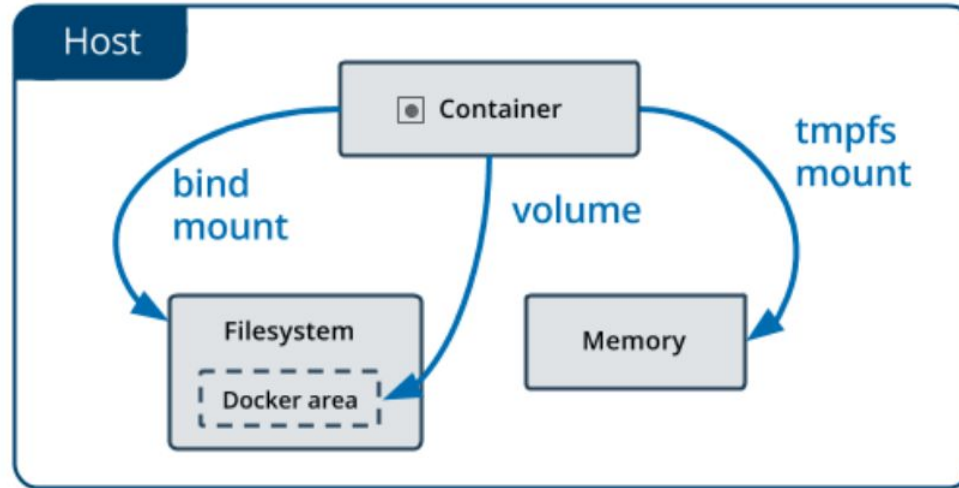

# What is a Volume

Special type of directory in a container typically referred to as a “data volume”

- Can be shared and reused among one or many containers
- Updates to an image won't affect a data volume
- Data volumes are persisted even after container deletion
- Volumes are OS agnostic. They can run on Linux and windows containers
- Volumes drivers allow us to store volumes on remote hosts or cloud providers.
- Volumes can be encrypted or to add other functionality
- A new volume content can be pre-populated by a container

# Manage Data in Docker

An easy way to visualize the difference among **volumes**, **bind mounts**, and **tmpfs** mounts is to think about where the data lives on the Docker host.

# Volumes - Demo

```
> docker run -dti --name alpine1 --mount target=/app alpine ash
```

```
> docker inspect alpine1
```

```
> docker stop alpine1 && docker rm alpine1
```

**STOP AND REMOVE**  
CLEAN UP

# Volumes - Demo

**Creating a VOLUME managed by docker FS and share it with multiple containers**

```
> docker volume create fs_shared
```

```
> docker volume ls
```

```
> docker run --rm -tdi --name alpine1 --mount source=fs_shared,target=/app alpine ash
```

```
> docker run --rm -tdi --name alpine2 --mount source=fs_shared,target=/app alpine ash
```

```
> docker run --rm -tdi --name alpine3 --mount source=fs_shared,target=/app alpine ash
```

# Volumes - Lab

Attach to running containers, create files and verify files gets updated on all containers

TIPS:

- Use previous slides to create volume and container that running with mount to that volume.
- Disconnect sequence: **Ctrl+p+Ctrl+q**

**STOP AND REMOVE**  
CLEAN UP

# BIND mounts

```
> docker run --rm -tdi -v `pwd`/source:/app alpine ash
```

```
> docker run --rm -tdi --mount type=bind,source=`pwd`/source,target=/app alpine ash
```

---

## BIND mounts using -V or --MOUNT?

Both will provide the same outcome but as -v /--volume exists since day 1 in docker and --mount was introduced since docker 17.06 it became normal and easier to use --mount.

# BIND MOUNTS - Lab

- **Create and manage bind mount:**
  - Create new host local project folder called “nice\_docker” and cd into it
    - Create 2 alpine containers and share new local folder called source1 using --mount
    - Create 2 alpine containers and share new local folder called source2 using -v
    - What happened when you tried creating a shared host folder with --mount without first creating the folder manually ? and what happened when you were using -v
  - Inspect the new volumes and containers
  - Validate shared folder by creating files and make sure the exists on both containers
  - Stop all docker containers and Make sure containers got deleted

# Running BootStrap app in a container - Lab

- **Hook SpringBoot Jar into a container:**
  - Create temp directory
  - Cd into your "temp" folder
    - Copy from your cloned git the demo artifact to ./source  
from solaredge-k8s-course/Docker/spring-boot-music/artifacts/spring-music.jar
  - **Run 1 new container**
    - Name: web\_api
    - Mount Using -v or --mount
      - temp/source
      - Target: /app
    - Image: **levep79/alpine-oraclejre8**
    - CMD: **java -jar -Dspring.profiles.active /app/spring-music.jar**

# Running BootStrap app in a container - Lab

Validate your work:

*docker ps, docker log, docker attach*

**Try Browsing from your host browser:** <http://<machine ip>:8080>

Did it worked?

What do you need to do to forward request to port 8080 and 8080 to your docker web\_api?

---

# Docker Networking

<https://docs.docker.com/network/>

# The Container Networking Model - CNM

---

# Network Native Network Driver

**Host** - With the **host** driver, a container uses the network stack of the host. There is no namespace separation, and all interfaces on the host can be used directly by the container.

**Bridge** - The basic and default driver which is used for standalone containers setup that need to communicate.

**Overlay** - Connect multiple docker daemons together and enable swarm (cluster) services to communicate with each other. This can be used to facilitate communication between swarm and standalone container or between two standalone containers on different docker daemons.

# Network Native Network Driver

**MACVLAN** - Allow us to assign a MAC address to a container for making it appear as physical device on our network. Best when you are migrating from a VM setup or need your containers to look like physical hosts on your network, each with a unique MAC address. Macvlan usually to be used with legacy or HW required product that must have a MAC and being directly connected to the physical network to operate.

**None** - The none driver gives a container its own networking stack and network namespace but does not configure interfaces inside the container. Without additional configuration, the container is completely isolated from the host networking stack.

# Networking - Lab

```
> docker network ls
```

```
> docker run --rm -tdi --name alpine1 alpine ash
```

```
> docker run --rm -tdi --name alpine2 alpine ash
```

1. Check that the containers are actually running
2. Inspect the network and see what containers are connected to it using  
**docker network inspect bridge**
3. Connect to one of the Alpine containers using **docker attach** or **exec** and ping the other container with IP and then with its name. What happened ?

# Networking - Lab

```
> docker network create dmz
```

```
> docker network inspect dmz
```

```
> docker run -tdi --rm --name network_test --network dmz alpine ash
```

```
> docker inspect network_test
```

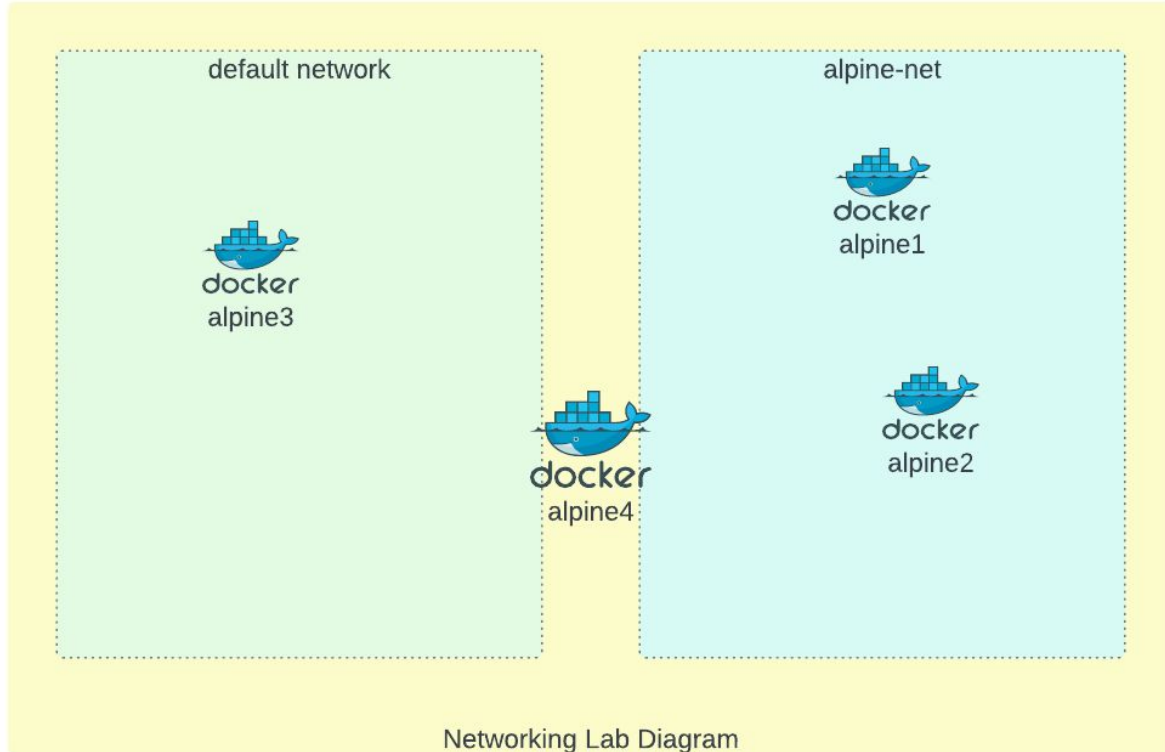

# Networking - Lab

1. Delete the previous containers (stop and then remove)
2. Create a newly user Defined network bridge named “**alpine-net**” and verify creation with **network ls** and than **Inspect** the network to see that no containers are connected
3. Create 4 new alpine containers with -dit and --network to the following network configuration
  - a. First two to: alpine-net
  - b. 3rd one to the **default bridge**
  - c. 4th one to **alpine-net &** to the **bridge** network (**trickey...**)

**Tip: *network connect...***

4. Inspect Network bridge and user defined network

# Lab Architecture Diagram

# Networking - Lab

5. Connect to alpine1 and try pinging to alpine1,2,3,4 with IP and DNS - What happened ?
6. Connect to alpine4 and try pinging to alpine1,2,3,4 with IP and DNS - What happened ?
7. Why?
8. Stop all containers , Remove them and delete the user defined network you created

---

# Docker Hub & Registry

# Local registry

```
> docker run -d -p 5000:5000 --name registry registry:2.7
```

```
> docker ps
```

```
> docker tag mysql localhost:5000/mysql
```

```
> docker push localhost:5000/mysql
```

---

### Image layers

Layer 1 - Base Image 196MB

Layer 2 - 226MB

Layer 3 -1.12kB

Layer 4 - 532B

Layer 5 - 80.6kB

Layer 6 - 0B

Layer 7 - 0B

Layer 8 - 0B

| Command    | Overview  |
|------------|---|
| FROM       | Specify base image  |
| RUN        | Execute specified command   |
| ENTRYPOINT | Specify the command to execute the container  |
| CMD        | Specify the command at the time of container execution (can be overwritten)               |
| COPY       | Simple copy of files / directories from host machine to container image                   |
| ADD        | COPY + unzip / download from URL ( <b>not recommended</b> )                               |
| ENV        | Add environment variables   |
| EXPOSE     | Open designated port  |
| WORKDIR    | Change current directory  |
| MAINTAINER | <b>deprecated</b><br>now LABEL maintainer="maintainer@example.com" should be specified as |

# CMD and ENTRYPOINT

- **CMD** sets default command and/or parameters, which can be overwritten from command line when docker container runs.
- **ENTRYPOINT** configures a container that will run as an executable.

---

# Shell form

```
CMD echo "Hello world"
```

```
ENTRYPOINT echo "Hello world"
```

---

# Exec form

```
CMD ["/bin/echo", "Hello world"]
```

```
ENTRYPOINT ["/bin/echo", "Hello world"]
```

# how CMD and ENTRYPOINT interact

- Dockerfile should specify at least one of **CMD** or **ENTRYPOINT** commands.
- **ENTRYPOINT** should be defined when using the container as an executable.
- **CMD** should be used as a way of defining default arguments for an **ENTRYPOINT** command or for executing an ad-hoc command in a container.
- **CMD** will be overridden when running the container with alternative arguments.

# ADD and COPY

- COPY will work for most of the cases.
- ADD has all capabilities of COPY and has the following additional features:

Allows tar file auto-extraction in the image, for example,

```
ADD app.tar.gz /opt/var/myapp
```

Allows files to be downloaded from a remote URL.

# ENV

Environment variables (declared with the **ENV** statement) can also be used in certain instructions as variables to be interpreted by the Dockerfile.

```
FROM busybox
```

```
ENV FOO=/bar
```

```
WORKDIR ${FOO}    # WORKDIR /bar
```

```
ADD . $FOO        # ADD . /bar
```

```
COPY \ $FOO /quux # COPY $FOO /quux
```

# USER

If a service can run without privileges, use **USER** to change to a non-root user. Start by creating the user and group in the Dockerfile with something like

```
RUN groupadd -r postgres && useradd --no-log-init -r -g postgres  
postgres
```

Avoid installing or using **sudo** as it has unpredictable TTY and signal-forwarding behavior that can cause problems. If you absolutely need functionality similar to **sudo**, such as **initializing the daemon as root but running it as non-root**, consider using “**gosu**”.

# BuildKit

BuildKit provides new functionality and improves your builds' performance. It also introduces support for handling more complex scenarios:

- Detect and skip executing unused build stages
- Parallelize building independent build stages
- Incrementally transfer only the changed files in your build context between builds
- Detect and skip transferring unused files in your build context
- Use Dockerfile frontend implementations with many new features
- Avoid side effects with rest of the API (intermediate images and containers)
- Prioritize your build cache for automatic pruning

[https://docs.docker.com/develop/develop-images/build\\_enhancements/](https://docs.docker.com/develop/develop-images/build_enhancements/)

# Import and export images

Docker images can be saved using image save command to a .tar file:

```
> docker image save helloworld > helloworld.tar
```

These tar files can then be imported using load command:

```
> docker image load -i helloworld.tar
```

# Docker Compose

<https://docs.docker.com/compose/>

# Docker-compose

Docker compose manages our application lifecycle

# Docker-compose

Compose is a tool for defining and running **multi-container Docker applications**. With Compose, you use a YAML file to configure your application's services. Then, with a single command, you create and start all the services from your configuration.

**It also has commands for managing the whole lifecycle of your application:**

- Start, stop, and rebuild services
- View the status of running services
- Stream the log output of running services
- Run a one-off command on a service

# Why do we need docker compose?

Imagine managing this manually

# Why do we need docker compose?

Using `docker-compose.yml` we can define

- Networking
- Dependencies between services
- Environments
- What makes up a role and its components
- Manage each application services we got

# Docker compose flow

Build Services  
(dockerfiles)

Generate images

Start our services

Take them down

With Compose, you use a YAML file to configure your application's services.

```
version: "3.9" # optional since v1.27.0
services:
  web:
    build: .
    ports:
      - "5000:5000"
    volumes:
      - ./code
      - logvolume01:/var/log
    links:
      - redis
  redis:
    image: redis
volumes:
  logvolume01: {}
```

---

With a single command, you create and start all the services from your configuration.

```
$ docker-compose up
```

or daemon mode:

```
$ docker-compose up -d
```

# Using Compose is basically three-step

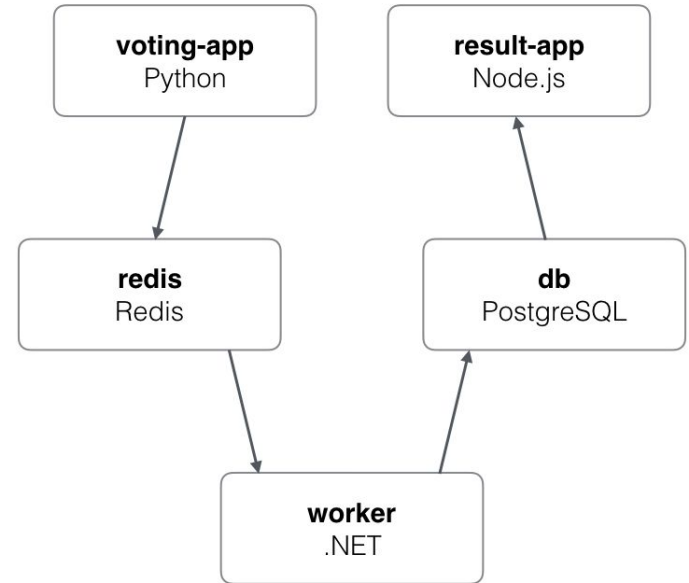

1. Define your app's environment with a Dockerfile so it can be reproduced anywhere.
2. Define the services that make up your app in `docker-compose.yml` so they can be run together in an isolated environment.
3. Run `docker-compose up` and Compose starts and runs your entire app.

---

# Demo

## Demo 2 - The Voting App

1. **Voting-App:** Frontend of the application written in Python, used by users to cast their votes.
2. **Redis:** In-memory database, used as intermediate storage.
3. **Worker:** .Net service, used to fetch votes from Redis and store in Postres database.
4. **DB:** PostgreSQL database, used as database.
5. **Result-App:** Frontend of the application written in Node.js, displays the voting results.

## Demo 2 - The Voting App

```
> docker-compose up
> docker ps -a --format="table {{.Names}}\t{{.Image}}\t{{.Ports}}"
> docker-compose up -d
> docker-compose down
> docker-compose start
> docker-compose stop
> docker-compose build
> docker-compose logs -f db
> docker-compose scale db=4
> docker-compose events
> docker-compose exec db bash
```
